# Canopy temperature (CT), stress degree days (SDD) as influenced by treatments and varieties in soybean

S.R. PATIL\*, N.R. SATPUTE¹ AND M.G. JADHAV Department of Agrometeorology, Marathwada Krishi Vidyapeeth, PARBHANI (M.S.) INDIA

**Abstract :** The experiment was laid out in Split Plot Design with three replications and two factors viz, date of sowing  $D_1$  (MW-27),  $D_2$  (MW-28),  $D_3$  (MW-29) and  $D_4$  (MW-30) and cultivars  $V_1$  (MAUS-47),  $V_2$  (MAUS-71),  $V_3$  (MAUS-81),  $V_4$  (MAUS-158),  $V_5$  (JS-9305) and  $V_6$  (JS-335) to find out the optimum sowing time for soybean genotypes. Experiment was carried out at research farm of Department of Agricultural Meteorology, Parbhani The canopy temperature designates the plant water stress. If the canopy temperature of soybean crop is greater, then soil moisture stress occurred in the field. Canopy temperature is one of the most reliable indicators of the crop water stress due to its direct relation with the plant water status. The highest mean canopy temperature (32.0°C) and (32.1°C) were observed in  $D_4$  (MW-30) date of sowing and genotype  $V_1$  (MAUS-47), respectively whereas stage  $P_{10}$  (maturity stage) indicated the highest mean canopy temperature 32.4°C. The lowest mean canopy temperature (30.9°C) and (30.7°C) were recorded in  $D_1$  (MW-27) date of sowing and genotype  $V_4$  (MAUS-158), respectively. Whereas stage  $P_1$  (emergence stage) indicated the lowest mean canopy temperature *i.e.* 30.30°C. The variety growth characters like emergence and final plant count, plant height, number of functional leaves, number of branches, number of pods, mean leaf area, leaf area index, dry matter, weight of pods per plant, weight of grain per plant, 1000 seed weight (test weight), grain yield, straw yield and biological yield were observed maximum in  $D_1$  (MW-27) date of sowing and in cultivar  $V_4$  (MAUS-158). Whereas, minimum observed in  $D_4$  (MW-30) date of sowing and cultivar  $V_4$  (MAUS-47).

Key Words: Canopy temperature, Stress degree days, Varieties, Soybean

## Introduction

In Maharashtra mainly the cultivation of soybean is as rainfed crop. It is the common experience of farmer and scientist that the rainfall at the maturity leads to the loss of seeds besides deterioration of seed quality. Thus, it is observed that harvesting period of soybean is coupled with post monsoon rains resulting in the loss of seed and its quality. In the past years, it has been observed that germination of seeds was considerably reduced to 11 to 20 per cent (Anonymous, 2000). This has alarmed for finding proper time for sowing so as to skip the crops from rains at

harvest. Performance of the crop has been reported to be highly governed by timely sowing and spatial arrangement (Sharma *et al.*, 1984). Delayed sowing of soybean not only resulted in yield reduction (Karmarkar and Bhatnagar, 1995) but also deteriorating the quality in respect to oil and protein content (Billare *et al.*, 2000). The temperature is an important meteorological variables that affect plant growth and development (Londe and Woodward, 1988). Day light or bright sunshine hours play an important role in growth and development of soybean crop. Same varieties flower in less than 30 days after emergence if exposed to day light less than twelve hours (Beard and Knowles, 1973).

# MATERIAL AND METHODS

The present investigation was carried out by laying out experiment on soybean with objective to study the performance of soybean (*Glycine max* L.) genotypes under varied weather conditions at Parbhani, Maharashtra. The experiment was conducted during *Kharif* season of 2010-2011, with Split Plot Design, Three replications and 24 treatments [Main treatment (sowing dates 4) × Sub treatment (Cultivar 6)].

# RESULTS AND DISCUSSION

The data collected during the investigation were analyzed by using appropriate statistical methods.

## Mean leaf area per plant (dm²):

The data on mean leaf area (dm²) per plant as influenced by different treatments at 15 days interval are presented in Table 1.

## Date of sowing:

The data on mean leaf area (dm²) per plant was influenced significantly by different date of sowing, at all stages of crop growth. Mean leaf area was observed significantly more in  $D_1$  (MW-27) than other treatments.

## **Cultivars:**

The mean leaf area was influenced significantly by different cultivars at all stages of crop growth. Mean leaf area was observed significantly more in  $D_1$  (MW-27) than other treatments.

## Interaction ( $D \times V$ ):

The interaction effect between date of sowing and different cultivars was found to be non-significant at all stages.

## Dry matter per plant (g/plant):

The data on mean dry matter per plant (g/plant) as influenced by different treatments at 15 days of interval are presented in Table 1. It was observed that mean dry matter per plant (g/plant) increased continuously up to 75 DAS of crop but later it decreased.

## Date of sowing:

The data presented in Table 1 indicate that the production was influenced significantly by different dates of sowing at all stages of crop growth. Dry matter was observed significantly more in D<sub>1</sub> (MW-27) than the other dates of sowing.

#### **Cultivars:**

The mean dry matter production was influenced

significantly by different cultivars at all stages of crop growth. The cultivar  $V_4$  (MAUS-158) produced higher dry matters than other cultivars.

#### Interaction ( $D \times V$ ):

The interaction effect between date of sowing and different cultivars was found to be non-significant at all stages.

#### **Growth analysis:**

#### Mean leaf area index:

The data on mean leaf area index (LAI) per plant as influenced by different treatments at 15 days interval are presented in Table 1.

#### Date of sowing:

The data on mean leaf area index (LAI) per plant was influenced significantly by different dates of sowing at all stages of crop growth. Mean leaf area was significantly more in  $D_{+}$  (MW-27) than other treatments.

# Cultivars:

The mean leaf area index was influenced significantly by different cultivars at all stages of crop growth.  $V_4$  (MAUS-158) produced more leaf area than other cultivars.

#### Grain yield (kg/ha):

The data regarding grain yield are presented in Table 2.

## Date of sowing:

The data on grain yield Table 2 indicated that the crop sown in  $D_1$  MW-27 (02-08 July) recorded higher grain yield (2876 kg/ha) and found significantly superior over other treatments whereas the lowest yield was recorded in treatment  $D_4$  (23-29 July). The crop sown in second week of July recorded low seed yield, dry spell resulted in low germination of crop. Over all, this year the crop recorded highest yield due to ample soil moisture during crop growing period.

#### Cultivars:

Statistical analysis of soybean cultivars showed significant results. During this year, variety MAUS-158 ( $V_4$ ) produced higher grain yield (2579 kg/ha) and was found significantly superior over remaining treatments. Whereas, the variety  $V_1$  (MAUS-47) produced lowest grain yield (1870 kg/ha) (Table 2).

#### Interaction:

The interaction effect between date of sowing and different cultivars was found to be non-significant at all stages and the results to that effect are presented in Table 2.

#### Soil moisture studies:

The data on soil moisture at different sowing dates of soybean crop from sowing to maturity are presented in Table 2. The data on soil moisture revealed that the soil moisture in  $D_1$  (MW-27) sowing dates treatment was on an average more than rest of the treatments, while in  $D_2$  (MW-28) and  $D_4$  (MW-30) sowing date treatments, the soil moisture stress at early growth stages was noticed, due to the yield of soybean crop was affected. The differences in soil moisture of the genotypes were significant at all stages. The soil moisture was significant

at all stages. The soil moisture content showed consistent increasing from 15 DAS to 45 DAS and then continuously decreased upto harvest of crop. At 45 DAS, the mean soil moisture was 35.34 per cent while at harvest the mean soil moisture was 26.00 per cent (Table 2).

## Canopy temperature $({}^{0}C)$ :

Canopy temperature for soybean crop under different sowing dates and varieties from sowing to maturity are presented in Table 3.

## Canopy temperature (°C) at different phenophases:

Data of Table 3 indicate that there were significant differences in canopy temperature at each phenophase of different dates of sowing and different cultivars. The canopy temperature was higher under stressed conditions as compared to unstressed conditions throughout the crop growth period. As per the date of sowing and different cultivars, the highest mean canopy temperature (32.0°C) and (32.1°C) were observed in D<sub>4</sub> date of sowing and V<sub>1</sub> (MAUS-47) genotype, respectively. Whereas stage P<sub>10</sub> (maturity stage) indicated the highest mean canopy temperature *i.e.* 32.4°C.

The canopy temperature designates the plant water stress. If the canopy temperature of soybean crop is greater, then soil moisture stress occurred in the field. Canopy temperature is one of the most reliable indicators of the crop water stress due to its direct relation with the plant water status. As per the date of sowing and variety, the mean lowest canopy temperature (30.9°C) and (30.7°C) recorded in D<sub>1</sub> date of sowing and genotype V<sub>4</sub> (MAUS-158), respectively (Table 3). Whereas P<sub>4</sub> (emergence stage) indicated the lowest mean canopy temperature i.e. 30.3°C. The data presented in Table 3 revealed that the average canopy temperature ranged from 30.3°C to 32.4°C in P<sub>1</sub> to P<sub>10</sub> stage (emergence to maturity). The canopy temperature was less than air temperature because of the occurrence of rainfall in all stages except only P<sub>10</sub> stage (maturity stage). While in maturity stage, canopy temperature was more than air temperature so there was moisture stress observed. Similar results were reported by Singh and Kanemasu (1983), Idso (1982) and Zhang Wen-Zhang et al. (2007).

# Canopy-air temperature (Tc-Ta) difference during phenophases:

The data pertaining to canopy-air temperature differential (Tc-Ta) during crop growth period in all dates of sowing and different cultivars are presented in Table 4. The Tc-Ta values were recorded in similar fashion as that of canopy temperature in all dates of sowing and genotypes. The average Tc-Ta values ranged from  $-2.9^{\circ}$ C to  $0.1^{\circ}$ C in  $P_1$  to  $P_{10}$  stage.

In maturity stage (P<sub>10</sub>) there was significant difference observed in all dates of sowing and genotypes. The P<sub>10</sub> stage showed higher positive (Tc - Ta) difference (0.1°C), which showed the soil moisture stress in P<sub>10</sub> stage. While in other stages, rainfall was occurred, so that Tc-Ta were negative which showed no any moisture stress in remaining stage except P<sub>10</sub> stage (maturity stage). The highest (Tc-Ta) difference was observed in P<sub>10</sub> stage in all dates of sowing and genotypes. Whereas, the lowest (Tc - Ta) difference was observed in P<sub>1</sub> (emergence stage) in all dates of sowing and genotypes. The similar results were reported by Ajayi and Pandey (1983) and Idso (1982).

## **Conclusion:**

It was found that the highest canopy temperature was observed in D<sub>4</sub> (MW-30) i.e. 32.0°C and cultivar V<sub>1</sub> (MAUS-47) i.e. 32.1°C due to bright sunshine and clear weather. Lowest canopy temperature was recorded in D<sub>1</sub> (MW-27) i.e. 30.9°C and cultivar V<sub>4</sub> (MAUS-158) i.e. 30.7°C. So, no any moisture stress observed in all phenophases stage except P<sub>10</sub> (maturity stage). In P<sub>10</sub> stage canopy temperature was more than air temperature so moisture stress was observed there.
