Genotype x environment interaction of flowering characters under moisture stress condition in winter maize

Suresh Prasad Singh* and P.B. Jha

Department of Plant Breeding, Rajendra Agricultural University, PUSA, SAMASTIPUR (BIHAR) INDIA

ABSTRACT

Genotype (G) x Environment (E) interaction of maize genotypes for anthesis-silking interval (ASI), tassel condensation (TC) and tassel vigour index (TVI) were studied under four diverse environments of sowing dates and moisture regimes. Highly significant mean squares due to genotypes, environments and G x E (linear) were observed for all the flowering traits. The crosses $P_1 x P_5 (G_{15} C_{22} MH148-1-1-1-6-3-BB x Pop27-S_4-4U-1-3)$ and $P_5 x P_{10}$ (Pop27-S₄-4U-1-3 x CML 117) were identified as tolerant to moisture stress as they were having lesser ASI with condensed tassel and high yield. However, three crosses, namely, $P_1 x P_{10} (G_{15} C_{22} MH148-1-1-1-6-3-BB x CML 117)$, $P_2 x P_{10}$ (Pool 21 Sequia best SYN CoF₂ x CML 117) and $P_5 x P_6$ [Pop 27-S₄-4U-1-3 x Pop 147(EEY DMR) S₁-117-3] exhibited high yield with minimum ASI over environments which may be exploited during winter season of Bihar.

Key words : Anthesis-silking interval, Tassel condensation, Tassel vigour index, Maize.

INTRODUCTION

In India, maize is cultivated throughout the year which is characterized by erratic rainfall and moisture stress. Moisture stress/ drought is a major factor responsible for limiting maize production and productivity in developing world. Edmeades *et. al.* (1992) have estimated about 15% global annual losses of maize production due to drought. Therefore, it is essential to develop a variety/genotype endowed with high degree of stability for flowering characters like ASI, tassel condensation and tassel vigour index to achieve high fertilization rate and ultimately good production & productivity. Moisture stress, if occurred just before or during the flowering period, a delay in silking is observed resulting in an increase in the period of anthesis-silking interval (Rabaut *et. al.*,1996), and decreased seed setting even if pollination occurs (Bassetti and Westgate,1993), resulting into decrease in grain yield.

MATERIALS AND METHODS

The experimental material consisted of ten genetically diverse and advanced generations maize inbred lines possessing different levels of tolerance to moisture stress (Singh and Jha, 2004). Diallel mating design was adopted to generate forty-five F_1 s. Ten parents along with forty-five F_1 s and two checks (Pusa Early Hybrid-1&2) were sown in randomized block deign, replicated three times with plot size of 4.5 m² and tested in four diverse environments, viz.,(i) Early sowing moisture non-stress (ii)Early sowing moisture stress (iii) Late sowing moisture non-stress and (iv)Late sowing moisture stress. The number of irrigation in moisture stress plot was reduced to one which was applied at knee high stage. The observations were recorded on three characters, namely, anthesis-silking interval, tassel condensation and tassel vigour index. The experimental data for ASI was recorded as per plot basis, whereas TC and TVI were recorded on ten competitive plants in each plot. Mean value of each plot was used for statistical analysis. The stability analysis was carried out as per method by Eberhart and Russell (1966). Genotypes having lower values of ASI and TVI, and higher value of TC were considered as desirable.

RESULTS AND DISCUSSION

The analysis of variance for design of experiment over environments revealed highly significant mean squares due to genotypes, environments and genotype x environment interaction for all the three traits included with study indicating the existence of significant difference among genotypes, environments and their interactions with environments (Table-1) Among the three flowering traits, only tassel condensation exhibited significant pooled deviation as well as G x E (linear) inferred that part of variability due to G x E is unpredictable in nature. Menkir and Akintude (2001) reported that moisture deficit significantly affected the ASI.

 $^{*},\,^{**}\,$: Significant at 5 % and 1% level of significance, respectively.

The average interval between days to anthesis and silking varied from 4.92(P₅) to 6.50 (P₈ x P₁₀) (Table-2). Lower ASI than the grand mean associated with unit regression coefficient was observed in P₁, P₄, P₅ and P₁₀ parents, P₁ x P₂, P₁ x P₅, P₁ x P₆, P₁ x P₇, P₁ x P₉, P₁ x P₁₀, P₂ x P₉, P₂ x P₁₀, P₃ x P₅, P₄ x P₉, P₅ x P₆, P₅ x P₇, P₅ x P₁₀, P₇ x P₈ and PEH-2 crosses. Of these, the crosses P₁ x P₂, P₁ x P₅, P₁ x P₆, P₁ x P₆, P₁ x P₆, P₁ x P₆, P₁ x P₁₀, P₂ x P₁₀, P₅ x P₆ and P₉ x P₁₀ were comparatively higher yielder, whereas PEH-2 was the average yielder. Therefore, these crosses were identified as stable genotypes over environments for ASI along with high/average yielding capacity. Similarly, less ASI with regression coefficient significantly lower than unity was found in P₂, P₃, and P₉ parents, P₁ x P₄, P₂ x P₃ and P₂ x P₈ crosses. Of these, only P₁ x P₄ was average yielder, therefore, this cross would be suitable under unfavourable environments for having reduced ASI. Furthermore, the parents P₂, P₃ and P₉ may be utilized to develop high yielding crosses with lower ASI under moisture stress condition.

The average tassel condensation ranged between 1.7 (P₄ x P₇₎ to 2.49 (P₁ x P₁₀). Higher tassel condensation associated with unit regression coefficient and non-significant deviation was exhibited only by two crosses, viz., P₁ x P₄ and P₃ x P₈. Of these two crosses, P₁ x P₄ was average yielder, therefore, it was identified as average stable genotype for TC associated with average yielding ability. In the same way, the crosses P₁ x P₅, P₃ x P₇ and P₁ x P₁₀ exhibited condensed tassel clubbed with significantly lower regression coefficient than unity and non-significant deviation. Out of these, P₁ x P₅ and P₆ x P₁₀ were the high yielding crosses, therefore, these crosses could be suitable under moisture stress condition.

The trait TVI varied between 26.80 (P₄ X P₉) to 46.25 (P₁ x P₂). The lesser TVI than grand mean accompanied with unit regression coefficient was observed in P₃, P₁ x P₃, P₁ x P₇, P₁ x P₈, P₂ x P₆, P₃ x P₇, P₃ x P₈, P₃ x P₉, P₄ x P₆, P₄ x P₇, P₄ x P₈, P₄ x P₉, P₅ x P₇, P₆ x P₇, P₆ x P₈, P₄ x P₉, P₅ x P₇, P₆ x P₇, P₆ x P₈, P₄ x P₉, Of these, the crosses P₁ x P₃, P₄ x P₇, P₄ x P₈, P₅ x P₇, P₆ x P₈, and P₆ x P₉ were the average yielder. Therefore, these crosses were recognized as stable genotypes for lower TVI along with average yield over the environments. However, the parents P₁ P₂, P₄, P₅, P₆, P₈, P₉, and P₁₀, and cross P₄ x P₅ were having the lower TVI value associated with regression coefficient significantly lower than unity. The cross P₄ x P₅ was also good yielder, therefore, it may be useful under unfavourable environment. The cross P₁ x P₄ among the average yielder genotypes was found to be better cross with less ASI under unfavourable environments and average stability for TC and TVI. However, P₁ x P₅ and P₅ x P₁₀ being high yielder with condensed tassel under stress environments also exhibited less interval between silking and anthesis. The parents (P₁, P₅ and P₁₀) involved in these two crosses were the good general combiners for yield and ASI which indicated the preponderance of additive type of gene action and could be utilized for further breeding programme. Keeping in view the importance of ASI than TC and TVI, the crosses, P₁ x P₂, P₁ x P₆, P₁ x P₁₀, P₂ x P₁₀, P₄ x P₅, P₅ x P₆ and P₅ x P₇ were identified as better crosses for ASI with high average grain yield.
