#### Abstract

Fifty genotypes of muskmelon (Cucumis melo L.) were evaluated for stability with respect to yield /ha, fruit length, fruit diameter, flesh thickness, $\mathrm{F}: \mathrm{C}$ ratio, fruit shape index and total soluble solids in three consecutive environments. The mean sum of squares due to genotypes, when tested against GxE and pooled deviation were highly significant for all the traits studied. Environmental variances, when tested against $G \times \mathrm{E}$ were also highly significant for all the traits indicating genetic variability among the genotypes and environments were effective in influencing the performance of the genotypes except $\mathrm{F}: \mathrm{C}$ ratio. The mean sum of squares due to $\mathrm{G} \times \mathrm{E}$ interaction, when tested against pooled deviation was highly significant for all the attributes. However, $G \times \mathrm{E}(\mathrm{L})$ effects were found to be highly significant for all the attributes indicated that major components of differences in stability was due to both linear and non linear components and the performance can be predicted over the environments except $\mathrm{F}: \mathrm{C}$ ratio and fruit shape index. The non-linear components (pooled deviation) were found to be significant for all the characters except flesh thickness. Based on the environmental indices, the environment $\mathrm{E}_{3}$ was most favourable for all the characters under studied except $\mathrm{F}: \mathrm{C}$ ratio. Considering the stability parameters of individual genotypes, it is revealed that the genotypes DVRM-2 and IAM Mono-1-1 had regression coefficient bi $\cong 1$ with non-significant deviation from regression ( $\mathrm{S}^{2} \mathrm{di}$ ) displayed wider stability for almost all the traits except fruit shape index and these genotypes can be utilized in further breeding improvement programmes.

Key words : Muskmelon, Genotype x Environment, Stability, Yield and quality characters.

In India, muskmelon (Cucumis melo L.) is one of the most important desert cucurbits grown extensively both in the garden land as well as riverbeds-an indigenously developed cucurbits growing system. Precise knowledge of the nature and magnitude of genotype $x$ environment interaction is very important in understanding the stability of different traits of a particular genotype, before it has recommended for commercial cultivation. The different sources of variation including genotype x environment interaction are of great importance to the plant breeders for deciding appropriate testing and selection procedure for planning an efficient plant-breeding programme.

The ultimate aim of plant breeder is to evolve cultivars of high yield potential with consistent performance over diverse environments. Compared with most of the vegetables crops, muskmelons are extremely susceptible to environmental variation and genotype x environment interaction may be responsible for lack of widely adapted cultivars (Timothy et al., 1980). The present study was, therefore, aimed to screen and isolate promising and potential genotypes of muskmelon (Cucumis melo L.) possessing stable performance over varying environmental conditions.

## MATERIALS AND METHODS

The mean performance of fifty genotypes of muskmelon consisting of all India level germplasm collections and recommended varieties were evaluated in Randomized Block Design with three replications in three different environments i.e. early kharif ( $\mathrm{E}_{1}-4^{\text {th }}$ April, 1999), rabi ( $\mathrm{E}_{2}-18^{\mathrm{th}}$ November, 1999) and summer (E3$21^{\text {st }}$ February, 2000) at Experimental Farm, Department of Horticulture, Mahatma Phule Krishi Vidyapeeth, Rahuri.

The plot size was kept at $2.00 \times 4.20 \mathrm{~m}^{2}$. The channels were prepared by keeping the distance of 2.00 $m$ between the two channels. Seeds were directly sown on hills spaced at 60 cm . Seven hills/plants in each genotypes in each replication were maintained. After germination, two seedlings were retained at each hill and data were recorded on five plants in each genotype in each replication. All cultural practices recommended for this crop were adopted timely in all three environments/ growing seasons. Observations were recoded on yield/ ha, fruit length, fruit diameter, flesh thickness, F:C ratio, fruit shape index and total soluble solids. The data were analyzed to test the significance of genotype $x$
environmental interactions and stability parameters, regression coefficient (bi) and deviation from regression ( $\mathrm{S}^{2} \mathrm{di}$ ) were computed by the method suggested by Eberhart and Russel (1966).

## RESULTS AND DISCUSSION

## Analysis of variance:

The analysis of variance for stability representing the mean sum of squares due to different sources of variance presented in Table 1. Effects due to genotypes, when tested against $G \times E$ and pooled deviation, were highly significant for all the characters studied. Environmental variances, when tested against G x E, were also highly significant for all the traits except F : C ratio. This indicates that the presence of genetic variability among the genotypes and environments. Gx E interaction, when tested against pooled error, was found to be highly significant for all the traits. Environmental (linear) effects and pooled deviation were highly significant for all the characters, except $\mathrm{F}: \mathrm{C}$ ratio and flesh thickness, respectively. However, genotype x environment (linear) effects found significant for all the traits except F : C ratio and fruit shape index. This indicated that major component of differences in stability was due to both linear and nonlinear components and the performance can be predicted
over the environments (Kalloo et al., 1998). A stable variety is one, which should perform relatively better under adverse conditions and not so in favourable environments by Eberhart and Russel (1966). These results are conformity with the findings given by Timothy et al. (1980), Krishna Prasad et al. (1990), Rajput et al. (1994), Lal and Dhaliwal (1996), Varlakshmi and Reddy (1998), Krishna Prasad et al. (1999) and Krishna Prasad et al. (2000).

## Environmental indices:

Estimates of environmental indices ( Ij ) given in Table 2 revealed that, $\mathrm{E}_{3}$ was the most favourable environment for all the attributes except $\mathrm{F}: \mathrm{C}$ ratio while $\mathrm{E}_{1}$ and $\mathrm{E}_{2}$ were unfavourable for almost all the characters studied.

## Stability parameters:

The estimate of stability parameters for yield and quality contributing characters presented in Table 3 and 4. According to Eberhart and Russel (1966) model, stability judged by four criteria i.e. variety is general adaptable or stable if mean is high than population mean, bi $\cong 1$ or non-significant and $S^{2} d i \cong 0$ (least or nonsignificant); variety is adaptable under poor environment or above average stability if mean is high, bi<1 and

significant and $\mathrm{S}^{2} \mathrm{di} \cong 0$ (least or non-significant); variety is adaptable under favourable environment or below average stability if mean is high, bi>1 and significant and $\mathrm{S}^{2} \mathrm{di} \cong 0$ (least or non-significant) and variety is unstable if mean is high or low, bi is significant or non-significant and $\mathrm{S}^{2} \mathrm{di}$ is significant or $\mathrm{S}^{2} \mathrm{di} \neq 0$. In Finlay and Wilkinson's (1963) terminology, genotypes with high bi values have low stability and are specifically adapted to high yielding environments and conversely low bi values indicate a high stability and adaptation to low yielding environments.

## Yield per hectare (q):

Eleven genotypes had significant $\mathrm{S}^{2}$ di values indicating their unstability for this character, while 13 genotypes showed significant regression coefficient (bi). Thirteen genotypes viz., Pusa Madhuras, Monoecious-3, Punjab Rasila, 84-2, DVRM-2, VRM 29-1, VRM43-6-1, IAM Mono-1-1, Kajri, 124-1, 138 (Gotya), VRM42-4$1 \mathrm{~A}-1$ and 124 were recorded maximum yield per hectare than population mean ( 82.23 q ) with regression coefficient $\mathrm{bi} \cong 1$ and non-significant $\mathrm{S}^{2} \mathrm{di}$ values indicating their wider stability for this character. The genotypes, Hara Madhu and 140 (Kavit) had better performance than population mean with regression coefficient bi>1 and non-significant deviation from regression ( $\mathrm{S}^{2} \mathrm{di}$ ) indicating their below average stability i.e. adaptable to favourable environments.

## Fruit length:

Only two genotypes, notably 123-4 and 124-2 had significant $S^{2}$ di values indicating it's unstability for this character. Twenty-eight genotypes exhibited significant regression coefficient.

Ten genotypes viz., Hara Madhu, DVRM-2, VRM 29-1, VRM42-4-1A, IAM Mono-1-1, IAM82-11, IAM2, 136, 137 and Durgapura Madhu expressed maximum fruit length with non-significant $\mathrm{S}^{2}$ di values and regression coefficient around unity indicating their stability for this trait. Genotype VRM43-6-1 had regression coefficient less than one with non-significant $\mathrm{S}^{2}$ di and higher mean performance indicating above average stability i.e. adaptable to poor environment. Genotypes 122-2, 1224, 122-6, 124-1, 124-3, 138 (Gotya), 139, 140 (Kavit), VRM42-4-1A-1 and 124 had maximum fruit length with regression coefficient greater than one and non-significant $S^{2}$ di values expressed below average stability i.e. adaptability to favourable environments.

## Fruit diameter (cm):

Twenty genotypes showed significant regression coefficient while four genotypes (122-6, 123-4, 124-1 and

VRM42-4-1A-1) were found to have significant deviation from regression indicating their unstability for this trait.

Thirteen genotypes viz., Pusa Madhuras, Monoecious-3, Hara Madhu, Punjab Rasila, 84-2, DVRM2, VRM1-3 $\oplus$ A, VRM42-4-1A, IAM Mono-1-1, IAM 124, Kajri, IAM-2 and 137 recorded maximum fruit diameter with regression coefficient $\mathrm{bi} \cong 1$ and nonsignificant deviation from regression ( $\mathrm{S}^{2} \mathrm{di}$ ) values indicating their wider stability. Genotypes 124-2, 138 (Gotya), 139 and 140 (Kavit) had significantly bi>1 with higher mean and non-significant $S^{2}$ di indicating below average stability and suitability for favourable environments. However, VRM31-1-2, VRM43-6-1, IAM L-13, 85-14 CMM and IAM 85-5 recorded maximum fruit diameter with regression coefficient greater than one and non-significant $S^{2}$ di values indicating their above average stability and suitability for poor environments.

## Flesh thickness (cm):

Out of 50 genotypes, 25 genotypes had more flesh thickness than population mean ( 2.19 cm ). Thirteen genotypes viz., Pusa Madhuras, Monoecious-3, Hara Madhu, DVRM-2, VRM31-1-2, VRM42-4-1A, VRM43-6-1, IAM Mono-1-1, IAM 1-24, IAM-15, IAM 85-5, 133 and 138 (Gotya) recorded maximum flesh thickness than population mean with regression coefficient $\mathrm{bi} \cong 1$ and nonsignificant $S^{2}$ di values indicating their wider adaptability. Genotypes IAM-2, 123-4, 124-2, 129, 139, 140 (Kavit) and VRM42-4-1A had high mean performance with regression coefficient greater than unity (bi>1) and nonsignificant $\mathrm{S}^{2}$ di indicating below average stability and suitability for favourable environments. Genotypes Punjab Rasila, 131, 132, 135 and 137 had more thickness than population mean with regression coefficient less than unity ( $\mathrm{bi}<1$ ) and non-significant deviation from regression indicating their above average stability i.e. adaptable to poor environments.

## Flesh : cavity ratio:

Six genotypes had significant $\mathrm{S}^{2}$ di values indicating their unstability for this character. All the genotypes exhibited non-significant values of the linear components of G x E interaction except genotype 124-2. None of the genotypes was found below average as well as above average stability. Nineteen genotypes possessed higher F:C ratio than population mean with regression coefficient near to unity (bí́) and non-significant value of $S^{2} \mathrm{di}$ exhibited wider adaptability for this character.

## Fruit shape index:

Six genotypes viz. DVRM-2, 122-4, 122-6, 123-3,

[^1]124-1 and Durgapura Madhu had significant deviation from regression ( $\mathrm{S}^{2} \mathrm{di}$ ) indicating their unstability for this trait. The genotypes 84-2 (0.98), VRM1-3 $\oplus \mathrm{A}$ (1.01), IAM-15 (1.03), 85-14 CMM (0.99) and 140 (0.99) had round fruit shape with non-significant deviation from regression and regression coefficient near to the unity (biㅢ) indicating their wider adaptability to this trait.

## Total soluble solids:

Twenty-eight genotypes recorded higher total soluble solids than population mean ( $6.33 \%$ ). However, 11 genotypes exhibited significant deviation from regression indicating their unstability for this character. Genotypes DVRM-2, VRM1-3 $\oplus$ A, VRM1-3 $\oplus$ B, 132, 124 and 140 (Kavit) exhibited high mean performance coupled with regression coefficient near to unity ( $\mathrm{bi} \cong 1$ ) and nonsignificant deviation from regression indicating their wider adaptability for this trait.

Genotypes 129, 131 and 133 had higher total soluble solids with regression coefficient significantly less than one ( $b<1$ ) and non-significant $\mathrm{S}^{2}$ di values indicating their above average stability and adaptable to poor environments. However, 12 genotypes showed regression coefficient greater than unity (bi>1) with high mean performance and non-significant deviation from regression indicating their below average stability i.e. adaptable to favourable environments.

The present results are in close agreement reported by Krishna Prasad and Singh (1990), Lal and Dhaliwal (1996), Krishna Prasad et al. (1999), Shridhar and Hari Har Ram (1999), Chaubey et al. (2000) and Krishna Prasad et al. (2000) and highly emphasized the importance of above said parameters for determination of stability and adaptability of the genotypes/varieties.

## Acknowledgement:

The senior author wish to express sincere thanks to my Research Guide Dr. T.A. More, Former Head, Department of Horticulture, MPKV, Rahuri and Principal Investigator of an Indo-Israel Joint Research Project entitled "Enhancement of muskmelon resistance to diseases via breeding and transformation.", present Director, Central Institute for Arid Horticulture, Bikaner (Rajasthan) for providing necessary facilities, encouragement, and support in the conduct of study.
