ABSTRACT

Two seed lots of groundnut (*Arachis hypogaea* L.) *viz.*, fresh seed having high germination vigour and revalidated seed (low vigour) were subjected to pre-sowing seed treatments and their efficacy was evaluated during summer seasons of 2005, 2006 and 2007. Pre-sowing seed invigoration by hydration for 16 h and air drying at room temperature followed by dressing with Thiram (75 % DS) @ 0.25 per cent registered consistently and significantly higher pod yield than the untreated seeds in revalidated seed. The higher pod yield was resulted from significantly improved germination, speed of emergence, per cent field emergence, ultimately the better crop establishment and in turn higher plant stand. The beneficial effects of hydration followed by Thiram dressing was more pronounced in the low vigour seed lot (revalidated) than in the high vigour lot (fresh). The study highlighted the efficacy of hydro priming followed by Thiram dressing.

Key words : Groundnut, Hydro priming, Field emergence, Pod yield, Thiram

INTRODUCTION

Groundnut (Arachis hypogaea L.) is the most important oilseed crop and also a food crop of India. During the year 2005-06 it was grown in an area of 6.4 million hectare with annual production of 7.21 million tonnes (Anonymous, 2002-03). The overall productivity of this crop in India is quite low. Usually, farmers are using their own seed. Hence, the vigour and viability of seed are bound to deteriorate, which is pre-dominant in summer groundnut. The poor vigour and viability, many times combined with the adverse environmental conditions may result in poor crop establishment and ultimately the decreased yield. Sometimes non-availability of certified fresh seed may compel the use of old (revalidated) seed lot and consequently results in poor yield. Under the circumstances, seed invigoration treatments may help in proper crop establishment and avoid the substantial loss in the yield. Not only that but any stage of the seed *viz.*, breeder, foundation or certified can be given pre-sowing seed invigoration treatment for harvesting the greater quantity of the seed yield. This is most vital when seed is a costly input as in case of groundnut. A number of presowing seed invigoration treatments have shown better seedling performance and crop establishment, and ultimately increased yield in several crops. (Anonymous, 2003) and (ISTA 1999), including groundnut Jaswinder Singh et al. (2004) and Khan et al. (2002). In view of this, the present study was taken up to find out the impact of pre-sowing seed invigoration treatments for better crop establishment in summer groundnut.

MATERIALS AND METHODS

Two seed lots of groundnut viz., fresh seed lot (high vigour seed with germination percentage > 90%) and old seed lot (low vigour seed with almost MSCS level of germination-revalidated) was included in the study. Both seed lots of groundnut were subjected to seven presowing seed treatments namely hydration for 16 h followed by air drying at room temperature (T_1) , cold hydration for 72 h at 10° C and surface drying (T₂), hydration with 50 ppm GA, for 16 h followed by surface drying at room temperature (T_2) , osmoconditioning with PEG (poly ethylene glycol) solution (-10 bars) at 15°OC for seven days (T_{λ}) , hydration for 16 h and drying followed by dressing with Thiram (75% DS) @ 0.25 per cent (T_{s}), hydration with 2 % KH₂PO₄ (potassium dihydrogen phosphate) for 16 h followed by drying at room temperature (T_6) , and dry seeds without any treatment used as a control (T_0) . Two separate experiments using fresh and revalidated seed were conducted employing seven pre-sowing seed invigoration treatments in the field in Randomized Block Design (RBD) with four replications adopting the recommended package of practices during summer seasons of 2005, 2006 and 2007. Two hundred counted seeds were sown in four rows of 5 m length in each plot. This matches the recommendation of seed rate of 100 kg/ha in groundnut. For estimation of speed of emergence in the field trials, a number of normal seedlings emerged out per 100 seeds, daily were counted. The speed of field emergence was calculated as suggested by Maguire (1962).

	Number of normal	Number of normal	Number of normal
Speed of emergence =	Seedlings emerged	Seedlings emerged	Seedlings emerged
	days to first count	days to second count	days to final count

Final plant stand was recorded at maturity. Pod yields were recorded on plot basis and converted to pod yield per hectare. The treated seeds of both the lots were also tested for laboratory germination as per the procedure of ISTA rules Kundu and Basu (1981). After the final germination count, 10 normal seedlings from each replication were taken randomly, oven dried at 80° C for 17 h and weighed for seedling dry weight. The data of fresh and revalidated seed lots of groundnut were separately subjected to simple RBD analysis and pooled over years and results are presented in Table 1 (high vigour lot) and Table 2 (low vigour seed lot), respectively.

RESULTS AND DISCUSSION

In fresh seed lot of groundnut, significant differences

in per cent germination, speed of emergence, seedling dry weight, per cent field emergence, plant stand and pod yield were observed due to different pre-sowing seed treatments in individual years as well as in the pooled one but the treatment x year interaction was also significant for all the characters studied (Table 1). Although, presowing seed invigoration by hydration for 16 h and drying at room temperature followed by dressing with Thiram @ 0.25 per cent (FT_5) recorded the highest pod yield in all the three years as well as in the pooled one but the values were not significantly higher than the control in two out of three years. Nevertheless, pooled data exhibited significantly higher pod yield in this treatment as compared to untreated seeds when tested against interaction CD. The beneficial effects of this treatment (FT_5) were also found in respect to per cent germination, speed of emergence, seedling dry weight, per cent field emergence and final plant stand in all the three years. Hydration at room temperature (FT_1) or cold hydration (FT_2) did not

Where, R = Revalidated groundnut seed, T = Treatment; Y = Year.

show any significant differences when compared with control with regards to any of the parameters studied. Hydration with 50 ppm GA₃ (FT₃) and 2 % KH₂PO₄ (FT₆) for 16 h followed by surface drying were also found to have adverse effects on per cent germination, speed of emergence, per cent field emergence and pod yield as compared to control. Osmoconditioning (FT₄) treatment had highly detrimental effects resulting in inhibition of germination and in turn all the other parameters.

In the revalidated seed lot of groundnut (Table 2), significant differences were observed among the presowing seed treatments for per cent germination, speed of emergence, seedling dry weight, per cent field emergence, plant stand and pod yield in individual years as well as in pooled analysis, and the interaction (treatment x year) was also found significant. Among the pre-sowing seed treatments, hydro priming, followed by Thiram dressing @ 0.25 per cent (RT₅) produced consistently and significantly higher pod yield than untreated seeds in all the three years. Moreover, the value was significantly higher than the control with respect to pod yield in pooled analysis when tested against (Y x T) interaction CD. More or less similar trend of seed invigoration (RT_5) was observed in per cent germination, speed of emergence, seedling dry weight, per cent field emergence and final plant stand in individual as well as in pooled analysis over years. Results are in accordance with the reports in past Maguire (1962) and Mitra and Basu (1979). In the present study, the year x treatment interaction was found to be significant due to inconsistency in other treatments. As in case of fresh seed lot, hydro priming seed treatment (RT₁) prior to sowing did not show any significant effects as compared to control. The other pre-sowing seed treatments also did not manifest any significant superiority over control for pod yield and other attributes studied. On the contrary, many a times, an adverse effect was discernible. Most pronounced detrimental effect was observed due to osmoconditioning with PEG. The latter has been reported to be extremely detrimental, resulting in complete inhibition of germination Maguire, (1962).

The response to different pre-sowing treatments was almost similar in both fresh and revalidated seed lots. However, hydro priming followed by Thiram dressing with 2.5 g/kg seed was more effective in low vigour seed than in high vigour seed. Thus, pre-sowing treatment in low vigour seeds of groundnut with hydration for 16 h followed by air drying and Thiram dressing @ 0.25 per cent resulted in significantly higher germination, speed of emergence, per cent field emergence, ultimately better crop establishment and in turn increase in pod yield. There are reports of germination vigour promotion and ultimately the yield by hydro priming Narayanaswamy et al. (1996), Poonam Singh et al. (2002). and Thiram seed dressing in groundnut as well as other crops ISTA (1999), Maguire (1962), Mitra and Basu (1979). Ram et al. (2002), Subbaraman and Selvara (1989). Thiram appears to act not only as a fungicide but also as a promoter of germination vigour.
