

Genetic variability studies in chilli (*Capsicum annuum L.*)

■ MAHANTESH Y. JOGI, M.B. MADALAGERI, V.M. GANIGER, G. BHUVANESWARI, H.B. PATIL AND Y.K. KOTIKAL

SUMMARY

Genetic variability, heritability, genetic advance and genetic advance as a per cent over mean for thirty two characters were assessed by field evaluation of fifty chilli accessions at College of Horticulture, Bagalkot (Karnataka) during 2010-11. High degree of variation was observed for all characters. The difference between phenotypic co-efficient of variation and genotypic co-efficient of variation were found to be narrow for most of the traits. The high estimates of heritability was found for plant spread (N-S) at 60 days (64.27%) and 120 day (65.47%) and (E-W) at 60 days (60.56%), number of fruits per plant at first picking (98.20%), early yield (94.67%), late yield (95.62%) and total yield (91.37%). The fruit characters like fruit width (96.22%), stalk length (81.04%) and ten fruit weight (96.44%), chlorophyll-a (95.45%), chlorophyll-b (97.52%), total chlorophyll (97.87%) and ascorbic acid (98.30%), fresh red chilli yield (95.18%) and dry red chilli yield (93.71%), hundred seed weight (70.67%) and number of seeds per fruit (94.67%) had also recorded high heritability.

Key Words : Green chilli, Genetic advance, Heritability, Genotypic variance, Phenotypic variance

Chilli (*Capsicum annuum L.*) is an important spice cum vegetable crop grown in all parts of the world. It is native of Tropical America and Guatemala is the secondary centre of origin. The Portuguese introduced it into India in the later part of the 16th century (Pruthi, 1976). Chilli is the most economic additive to improve food acceptability. It is cultivated for its vegetable green fruits and dry chilli as the spice of commerce. It has different uses at matured green, red ripe and

dried stage. The pungency is due to the presence of a crystalline volatile alkaloid called capsaicin (8-methyl-N-vanillyl-6-enamide). Extract from the fruits is incorporated into pharmaceutical preparations and the colour oleoresin (capsanthin) obtained from fruits is used in the food processing industry.

Chilli is a rich source of vitamin C. It also contains vitamin A, vitamin B and minerals (Singh *et al.*, 2007). In India, dry chilli is grown over an area of 7.92 lakh hectares with a production of 12.23 lakh tonnes and the productivity of 1.5 tonnes per hectare (Anonymous, 2011). Indian chillies reach over 90 countries in the world. Sri Lanka, USA, UAE, Pakistan, Bangladesh, Saudi Arabia and Malaysia are the important markets for Indian chillies. The productivity of the crop is low and there is need for development of new varieties and hybrids with high productivity. The critical assessment of nature and magnitude of variability in the germplasm stock is one of the important pre-requisites for formulating effective breeding methods as the genetic improvement of any crop depends on magnitude of genetic variability and the extent of heritability of economically important characters, though the part played by environment in the expression of such character also needs to be taken into account. Much of the earlier works in chilli

were mainly directed towards the red chilli (Awasti *et al.*, 1970 and Hiremath and Mathapati, 1977). Information available on these aspects on green chilli is quite meagre (Basavaraj, 1997). Therefore, a field investigation was carried out with a view to study the genetic variability, heritability and genetic advance in green chilli yield and quality by assessing the chilli germplasm stock maintained at College of Horticulture,

Bagalkot (Karnataka).

MATERIAL AND METHODS

Fifty genetically diverse chilli accessions comprising of established varieties and advanced breeding lines were grown in a Randomized Block Design with two replications during

NS=Non-significant

Kharif 2010-11. Each experimental plot comprised of single row of ten plants. From each plot three plants were randomly selected for recording observations on plant height (cm), primary branches, secondary branches, tertiary branches, days to first flowering, days to fifty per cent flowering, days to fruit set, number of fruits per plant at first picking, fruit length (cm), fruit girth (cm), early yield, late yield and total green chilli yield per plant, red chilli yield, dry chilli yield and quality parameters. Genotypic co-efficient of variation and phenotypic

co-efficient of variation were computed by the method of Burton and Devane (1953). Heritability (broad sense), genetic advance (GA) and genetic advance as a per cent over mean (GAM) were worked by following the methods suggested by Falconer (1981) and Robinson *et al.* (1949).

RESULTS AND DISCUSSION

The analysis of variance was conducted to test significant differences among genotypes studied. The mean

sum of squares due to various sources for different character are presented in Table 1. The genotypic and phenotypic co-efficient of variability, heritability and genetic advance as per cent over mean (GAM) for each of the characters are presented in Table 2. High heritability with high GAM was recorded for most of growth as well as yield characters viz., number of fruits per plant, early yield, late yield and total yield indicating the predominance of additive gene components in governing these traits. Thus, there is ample scope for improving these characters based on direct selection from the genetic stock studied.

The difference between the genotypic co-efficient of variation (GCV) and phenotypic co-efficient of variation (PCV) were found to be narrow for most of the characters. The results suggest that these traits are least affected by environment and selection for these traits on phenotypic would be rewarding. For rest of the characters, the estimates of PCV were greater than GCV. This indicates that the variation for these traits is not only by genotypes but also due to environment. Selection based on phenotypes may mislead as their expression depends more on, environmental factors. Similar observations were reported in chilli by Shah *et al.* (1986) and Shirsat (1994).

In the present study, most of the characters exhibited high estimates of heritability except for plant height at 60 and 120 days, primary and secondary branches at 60 days and plant spread (E-W) at 120 and days to 50 per cent flowering, days to fruit set. The high estimates of heritability for days to first flowering (70.49%), number of fruits per plant at first picking (98.20%), total number of fruits per plant (95.64%), early yield (94.67%), late yield (95.62%), total yield (91.37%), fruit length (91.22%), fruit width (96.22%), stalk length (81.04%), ten fruit weight (96.44%), ascorbic acid (98.30%), chlorophyll-“a” (95.45%), chlorophyll-“b” (97.52%), total chlorophyll (97.87%), fresh weight of red chilli (95.18%), dry weight of red chilli (93.71%), hundred seeds weight (70.67%) and number of seeds per fruit (94.67%) suggest that selection will be effective for these characters. These results are in conformity with those of Sahoo *et al.* (1989) and Amarchandra *et al.* (1990). High heritability along with high genetic advance is an important factor for predicting the resultant effect for selecting the best individuals. In the present study, high heritability was accompanied with high values of genetic advance for early yield, late yield, total yield, ten fruit weight, ascorbic acid, fresh weight of red chilli and dry weight of red chilli indicating predominance of additive gene component. Thus, there is ample scope for improving these characters based on direct selection. High heritability with moderate genetic advance noticed for plant height at 120 days, tertiary branches at 60 and 120 days, plant spread (N-S) at 60 and 120 days, number of fruits per plant at first picking, ten fruit weight

implied equal importance of additive and non additive gene action. These results are in agreement with the earlier findings of Rani *et al.* (1996) and Shah *et al.* (1986). From the present (Table 3) study based on their *per se* performance the genotypes the top performing genotypes, HC - 0705, DCA - 199, EC - 28 DPS - 06 - 01, EC - 33 DCS - 06 - 02, HC - 0714, EC - 33 DCS - 06 - 01 and SSD can be further assessed for stability so as to exploit them for commercial cultivation.
